## 1 Quickstart

A short version to achieve the above is by using the preprocessed version of the dataset provided with this package. `data(guo)` is already preprocessed (using the method first mentioned), has its threshold set to a constant 15 and is ready to use. Since the platform's maximum amplification cycles are 40, that number can be used as upper border of the uncertainty range.

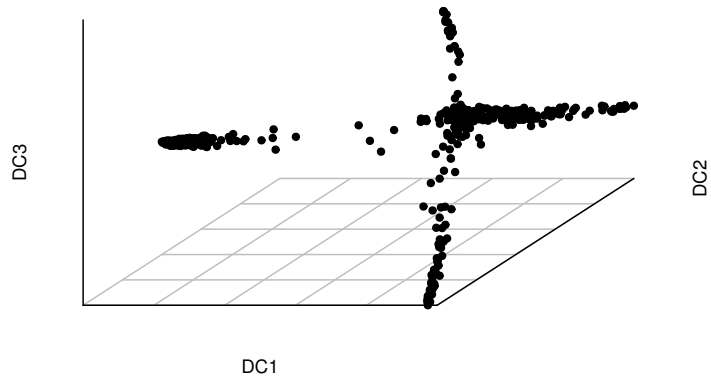

```
In [2]: library(destiny)
        data(guo)
```

It can be used directly for diffusion map creation:

```
In [3]: dm_guo <- DiffusionMap(guo, verbose = FALSE,
                               censor.val = 15, censor.range = c(15, 40))
        dm_guo
```

```
DiffusionMap (20 Diffusion components and 428 samples)
eigenvalues:   num [1:20] 0.955 0.847 0.784 0.764 0.687 ...
eigenvectors: num [1:428, 1:20] 0.119 0.117 0.104 0.111 0.116 ...
  ..colnames: chr [1:20] "DC1" "DC2" "DC3" "DC4" ...
optimal_sigma: num [1:428] 7.41 7.56 9.09 6.62 6.29 ...
distance:      chr "euclidean"
```

```
In [4]: plot(dm_guo, pch = 20)
```

using the annotation shows that the approximation worked

```
In [5]: palette(cube_helix(6))
        plot(dm_guo, col_by = 'num_cells', pch = 20,
              legend_main = 'Cell stage')
```
